

Prompt: Write a C program that will sort emails by priority from a CEO using a max heap (not from existing pre modules) with list based implementation

Claude: Generated a C file that contained the code used as a starting point for this assignment

Microsoft 365 Copilot: Below is a complete C program that satisfies the assignment requirements and avoids using any prebuilt heap libraries. The heap is implemented using an array-backed list (list-based implementation), with custom heap insertion and deletion operations

(code for each in respective pdfs)

Comparison: The Claude file incorrectly ordered the importance of people, which was something that needed to be changed. Claude also seemed to have issues with the prompts that were going to be read into it from the test file where Copilot could handle those. I chose to work with the Claude code since it was a better base and gave me more to work with adding the things that Copilot had and merging them, so it flowed better and still worked. I started correcting the order of the file and then going through the next and read commands to update them. The last thing I did was go back over the file and comment it myself to make sure I understood what was happening throughout it. Claude seems to have  $O(n)$  complexity for space Copilot seems to be the same.
